Table 1: All 60 eliminations: current debt and the debtor's own legal finance at the elimination decision. Money columns are game dollars; bank houses is a count.

Notes. One row per applied elimination: 56 declared bankruptcies and four automatic eliminations after a final mortgage. Owed is the current debt. Cash is cash on hand. Menu mort. adds the mortgage value of deeds mortgageable on the first menu screen, with no building sale. Access. own seq. adds the greedy own-action liquidation: sell houses, downgrade a hotel only while the bank holds at least four houses, then mortgage unlocked deeds, repeated. Full bound adds half the building cost per level and every unmortgaged mortgage value, ignoring the bank-house constraint. For automatic rows, all bounds are computed at the triggering decision state, before its action. Bank houses is the bank's house stock at that state. Pays debt reproduces the source field `avoidable`: *Yes* means an engine-verified own-action sequence can pay the current debt. It does not assert later survival, a rational alternative or a changed winner, and it assumes no help from another player. Route H/T/M counts houses sold, hotels sold and mortgages in the greedy sequence; the ordered sequence is in the source CSV and JSON. In G7 the hotel-sale rule binds: \$440 accessible against \$1,310 nominal under a \$750 debt.
